Package 'rgeedim'

February 2, 2026

Type Package

Title Search, Composite, and Download 'Google Earth Engine' Imagery with the 'Python' Module 'geedim'

Version 0.4.0

Maintainer Andrew Brown <brown.andrewg@gmail.com>

URL https://humus.rocks/rgeedim/, https://github.com/brownag/rgeedim, https://geedim.readthedocs.io/

BugReports https://github.com/brownag/rgeedim/issues

Repository CRAN

Description Search, composite, and download 'Google Earth Engine' imagery with 'reticulate' bindings for the 'Python' module 'geedim' by Dugal Harris. Read the 'geedim' documentation here: <https://geedim.readthedocs.io/>.
Wrapper functions are provided to make it more convenient to use 'geedim' to download images larger than the 'Google Earth Engine' size limit <https://developers.google.com/earth-engine/apidocs/ee-image-getdownloadurl>.
By default the ``High Volume'' API endpoint <https://developers.google.com/earth-engine/cloud/highvolume> is used to download data and this URL can be customized during initialization of the package.

SystemRequirements Python (>= 3.6.0)

Config/reticulate list(packages = list(list(package = ``earthengine-api''), list(package = ``geedim''), list(package = ``google-auth'')))

Contents

`earthengine` *Get Earth Engine* `Module(earthengine-api)` *Instance*

Description

Gets the `earthengine-api` module instance in use by `geedim` package in current session.

`gd_ee_version()` Gets the `earthengine-api` version using `importlib.metadata.version()`

Usage

```
earthengine()

gd_ee_version()
```

Value

character. Version Number.

`gd_authenticate` *Authenticate with Google Earth Engine using* `gcloud`*, "Notebook Authenticator" or other method*

Description

Calls `ee.Authenticate(...)` to create a local instance of persistent credentials for Google Earth Engine. These credentials are used on subsequent calls to `ee.Initialize(...)` via `gd_initialize()`.

Usage

```
gd_authenticate(
  authorization_code = NULL,
  quiet = FALSE,
  code_verifier = NULL,
  auth_mode = NULL,
  scopes = NULL,
  force = TRUE
)
```

Arguments

`authorization_code`	Default: `NULL`
`quiet`	Suppress warnings, errors, messages? Default: `FALSE`
`code_verifier`	Code verifier (required if `authorization_code` is specified). Default: `NULL`
`auth_mode`	One of `"notebook"`, `"colab"`, `"gcloud"`, `"gcloud-legacy"` or (default) `NULL` to guess based on the current environment.
`scopes`	List of scopes to use for authentication. Defaults `NULL` corresponds to `c('https://www.googleapis.com 'https://www.googleapis.com/auth/devstorage.full_control')`
`force`	Force authentication even if valid credentials exist? Default: `TRUE`

Details

This method should be called once to set up a machine/project with a particular authentication method.

- `auth_mode="gcloud"` (default) fetches credentials using `gcloud`. Requires installation of command-line Google Cloud tools; see https://cloud.google.com/cli for details. This mode will open a web page where you can sign into your Google Account, then a local JSON file will be stored in `gcloud` configuration folder with your credentials. These credentials will be used by any library that requests Application Default Credentials (ADC) which are preferred for long-term storage.

- auth_mode="notebook" argument is intended primarily for interactive or other short-term use. This mode will open a web page where you can sign into your Google Account to generate a short-term, revocable token to paste into the console prompt.
- auth_mode="appdefault" mode uses locally stored credentials gcloud configuration stored in 'application_default_credentials.json' or JSON file specified by GOOGLE_APPLICATION_CREDENTIALS environment variable.

Value

This function is primarily used for the side-effect of authentication with the 'Google Earth Engine' servers. Invisibly returns try-error on error.

Examples

```
## Not run:
# opens web page to complete authentication/provide authorization code
gd_authenticate(auth_mode = "notebook")

## End(Not run)
```

---

gd_band_names *Get Names of Layers in an Earth Engine Image*

Description

Calls bandNames() method from ee.Image class.

Usage

```
gd_band_names(x)
```

Arguments

x	a geedim.image.ImageAccessor (for geedim >= 2.0.0) or geedim.download.BaseImage (for geedim < 2.0.0) object, such as from gd_image_from_id(). See \link{geedim-versions} for more details.

Value

character. Vector of names of each layer in an image.

Examples

```
if (gd_is_initialized())
  gd_band_names(gd_image_from_id("USGS/SRTMGL1_003"))
```

gd_band_properties *Get Properties of Layers in an Earth Engine Image*

Description

Gets combined Earth Engine and STAC properties.

Usage

```
gd_band_properties(x)
```

Arguments

x	a geedim.image.ImageAccessor (for geedim >= 2.0.0) or geedim.download.BaseImage (for geedim < 2.0.0) object, such as from gd_image_from_id(). See \link{geedim-versions} for more details.

Value

list. Each element is a list that corresponds to a layer in x, each with one or more elements for properties of that layer.

Examples

```
if (gd_is_initialized())
  gd_band_properties(gd_image_from_id("USGS/SRTMGL1_003"))
```

gd_bbox *Prepare Bounding Box Region from X/Y Limits*

Description

Create a bounding box polygon Python object for use with gd_download(). The coordinates of the bounding box are expressed in WGS84 decimal degrees ("OGC:CRS84").

Usage

```
gd_bbox(...)
```

Arguments

...	One or more SpatRaster, SpatRasterCollection, SpatVector, SpatVectorProxy or SpatExtent objects (whose combined bounding box extent will be returned); or the following *named* numeric arguments: xmin/ymax/xmax/ymin. If these four limit arguments are not named they should be in the stated order.

Details

Expecting total of 4 bounding box arguments, If arguments are unnamed they should be in the following order: "xmin", "ymax", "xmax", "ymin".

Value

a *list* object describing a GeoJSON bounding rectangular polygon suitable for use as `regions` argument to `gd_download()` or `gd_search()`

Examples

```
gd_bbox(
  xmin = 5.744140,
  ymax = 50.18162,
  xmax = 6.528252,
  ymin = 49.44781
)
```

---

gd_composite *Composite an Image Collection*

Description

Create a composite image from elements of an image collection.

Usage

```
gd_composite(x, ...)
```

Arguments

`x`	an object inheriting from `geedim.collection.ImageCollectionAccessor` (for geedim >= 2.0.0) or `geedim.collection.MaskedCollection` (for geedim < 2.0.0), such as from `gd_search()` or `gd_collection_from_list()`. See `\link{geedim-versions}` for more details.
`...`	additional arguments to `geedim.collection.ImageCollectionAccessor$composite()`

Value

a composite `ee.image.Image` object

Examples

```
library(terra)

b <- terra::vect('POLYGON((-121.355 37.560,
                           -121.355 37.555,
                           -121.350 37.555,
                           -121.350 37.560,
                           -121.355 37.560))',
                 crs = "OGC:CRS84")

if (gd_is_initialized())
  gd_composite(gd_search(gd_collection_from_name("USGS/3DEP/1m"),
                         region = b),
               resampling = "bilinear")
```

`gd_download` *Download a Google Earth Engine Image*

Description

Download a Google Earth Engine Image

Usage

```
gd_download(
  x,
  filename = tempfile(fileext = ".tif"),
  region = NULL,
  composite = TRUE,
  overwrite = TRUE,
  silent = TRUE,
  ...
)
```

Arguments

`x`	ID or Name, or a reference to an object inheriting from `geedim.image.ImageAccessor` (for geedim >= 2.0.0) or `geedim.download.BaseImage` (for geedim < 2.0.0) or `geedim.collection.ImageCollectionAccessor` (for geedim >= 2.0.0) or `geedim.collection.MaskedCollection` (for geedim < 2.0.0). See `\link{geedim-versions}` for more details.
`filename`	path to output file, defaults to temporary GeoTIFF file path; if `composite=FALSE` then this path should be to a parent directory. File names will be calculated from the internal name of the image and the requested scale.

region	a GeoJSON-like list, or other R spatial object describing region of interest, see gd_region() and gd_bbox() for details. NULL region (default) will download the whole image.
composite	logical. Composite Image Collection into single image for download? Default: TRUE
overwrite	Overwrite existing file? Default: TRUE
silent	Silence errors? Default: TRUE
...	Additional arguments (e.g. scale) passed to geedim.image.ImageAccessor$toGeoTIFF(...) and, when composite=TRUE, geedim.collection.ImageCollectionAccessor$composite()

Details

The region argument is *optional* for downloading images. When downloading a composite Image Collection, you must specify region, scale and crs arguments. When downloading an image collection as a set of GeoTIFF files (composite=FALSE), then filename is the destination directory, and scale must be specified. The default resampling method in geedim is resampling="near" (Nearest Neighbor). Other options for resampling include: "average", "bicubic", "bilinear". See gd_resampling_methods().

Value

Invisible path to downloaded image, or try-error on error

See Also

gd_region() gd_bbox()

Examples

```
r <- gd_bbox(
  xmin = -121,
  xmax = -120.5,
  ymin = 38.5,
  ymax = 39
)

if (gd_is_initialized()) {
 x <- gd_image_from_id('CSP/ERGo/1_0/Global/SRTM_topoDiversity')
 tf <- tempfile(fileext = ".tif")

 # fast sample download at 10x aggregation (900m v.s. 90m)
 img <- gd_download(x, filename = tf,
                    region = r, scale = 900,
                    overwrite = TRUE, silent = FALSE)

 if (requireNamespace("terra")) {
   library(terra)
   f <- rast(img)
   plot(f[[1]])
```

```
  # inspect object
  f
 }
 unlink(tf)
}
```

---

gd_enum_names geedim *Enums*

Description

geedim Enums

Usage

```
gd_enum_names()

gd_enum_elements(enum = gd_enum_names())

gd_resampling_methods()

gd_cloud_mask_methods()

gd_composite_methods()

gd_export_types()

gd_spectral_distance_metrics()
```

Arguments

enum	Enum name, one or more of: "CloudMaskMethod", "CompositeMethod", "ResamplingMethod"

Value

gd_enum_names(): character vector containing names of Enums

gd_enum_elements(): element values of an Enum

gd_resampling_methods(): character vector of resampling methods (Enum "ResamplingMethod")

gd_cloud_mask_methods(): character vector of cloud mask methods (Enum "CloudMaskMethod")

gd_composite_methods(): character vector of composite methods (Enum "CompositeMethod")

gd_export_types(): character vector of export types (Enum "ExportType")

gd_spectral_distance_metrics(): character vector of spectral distance metrics (Enum "SpectralDistanceMetric")

Examples

```
if (gd_is_initialized())
 gd_enum_names()
```

```
if (gd_is_initialized())
 gd_enum_elements()
```

```
if (gd_is_initialized())
 gd_resampling_methods()
```

```
if (gd_is_initialized())
 gd_cloud_mask_methods()
```

```
if (gd_is_initialized())
 gd_composite_methods()
```

```
if (gd_is_initialized())
 gd_export_types()
```

```
if (gd_is_initialized())
 gd_spectral_distance_metrics()
```

`gd_export` *Export image to Earth Engine Asset, Google Cloud Storage Bucket, or Google Drive*

Description

Exports an encapsulated image to the destination specified by `type`, `folder` and `filename`

Usage

```
gd_export(
  x,
  filename,
  type = "drive",
  folder = dirname(filename),
  region,
  wait = TRUE,
  overwrite = TRUE,
  ...
)
```

Arguments

x	An object that inherits from geedim.image.ImageAccessor (for geedim >= 2.0.0) or geedim.download.BaseImage (for geedim < 2.0.0). See \link{geedim-versions} for more details.
filename	Output filename. If type is "asset" and folder is not specified, filename should be a valid Earth Engine asset ID.
type	Export type. Defaults to "drive"; other options include "asset", and "cloud". See gd_export_types()
folder	Destination folder. Defaults to dirname(filename).
region	Region e.g. from gd_bbox() or gd_region()
wait	Wait for completion? Default: TRUE
overwrite	Overwrite existing? Default: TRUE. Only supported for geedim >= 2.0.0.
...	Additional arguments to geedim.image.ImageAccessor.toGoogleCloud() (geedim >= 2.0.0) or geedim.download.BaseImage.export() (geedim 1.x.x)

Details

See the geedim.image.ImageAccessor.toGoogleCloud() documentation for details on additional arguments. Requires 'geedim' >1.6.0.

Value

an ee.batch.Task object

Examples

```
## Not run:
if (gd_is_initialized()) {
 r <- gd_bbox(
   xmin = -120.6032,
   xmax = -120.5377,
   ymin = 38.0807,
   ymax = 38.1043
 )
```

```
i <- gd_image_from_id('CSP/ERGo/1_0/US/CHILI')

## export to Google Drive (default `type="drive"`)
# res <- gd_export(i, filename = "RGEEDIM_TEST", scale = 100, region = r)

## export to `type="asset"`, then download by ID (stored in project assets)
# res <- gd_export(
#   i,
#   "RGEEDIM_TEST",
#   type = "asset",
#   folder = "rgeedim-demo",
#   scale = 100,
#   region = r
# )
# gd_download("projects/rgeedim-demo/assets/RGEEDIM_TEST", filename = "test.tif")

## export to Google Cloud Bucket with `type="cloud"`,
##   where `folder` is the bucket path without `"gs://"`
# res <- gd_export(i, filename = "RGEEDIM_TEST.tif", type = "cloud",
#                  folder = "your-bucket-name", scale = 100, region = r)
}

## End(Not run)
```

`gd_footprint` *Get Footprint of Masked Image*

Description

Gets GeoJSON-style list containing footprint of a `geedim.image.ImageAccessor` (for geedim >= 2.0.0) or `geedim.mask.MaskedImage` (for geedim < 2.0.0) object. See `\link{geedim-versions}` for more details.

Usage

```
gd_footprint(x)
```

Arguments

`x`	a `geedim.image.ImageAccessor` (for geedim >= 2.0.0) or `geedim.mask.MaskedImage` (for geedim < 2.0.0) object. See `\link{geedim-versions}` for more details.

Value

list.

Examples

```
if (gd_is_initialized())
  gd_footprint(gd_image_from_id("USGS/SRTMGL1_003"))
```

---

gd_get_asset *Get, Update, or Delete an Earth Engine Asset by ID*

Description

Get, Update, or Delete an Earth Engine Asset by ID

Usage

```
gd_get_asset(x, silent = FALSE)

gd_update_asset(
  x,
  asset,
  update = c("start_time", "end_time", "properties"),
  silent = FALSE
)

gd_delete_asset(x, silent = FALSE)
```

Arguments

x	Asset ID name
silent	Silence errors? Default: FALSE
asset	Used only for gd_update_asset(): a named list, with names representing elements of x to replace. Only "start_time", "end_time", and "properties" fields can be updated.
update	Used only for gd_update_asset(): A character vector of field names to update. Default: "start_time", and "end_time" to update timestamps; and "properties" to update all properties.

Value

try-error on error. gd_get_asset(): a named list containing information and properties of an Earth Engine asset

gd_update_asset(): This function is called for side-effects (updates the specified asset fields)

gd_delete_asset(): This function is called for side-effects (deletes the specified asset)

Examples

```
## Not run:
# get asset from project by ID
a <- gd_get_asset("projects/rgeedim-demo/assets/YOUR_ASSET_ID")

## End(Not run)
## Not run:
# change description in `"properties"`
a$properties$description <- "foo"

# update asset
gd_update_asset("projects/rgeedim-demo/assets/YOUR_ASSET_ID", a, "properties")

## End(Not run)
## Not run:
# remove an asset from project
gd_delete_asset("projects/rgeedim-demo/assets/YOUR_ASSET_ID")

## End(Not run)
```

`gd_image_from_id` *Reference Google Earth Engine Image or Image Collection by ID or Name*

Description

Create references to a Google Earth Engine Image or Image Collection based on IDs or names, or combine Images into Image Collections.

Usage

```
gd_image_from_id(x)

gd_collection_from_name(x)

gd_collection_from_list(x)

gd_asset_id(filename, folder = NULL)

gd_list_assets(parent)
```

Arguments

`x`	character. `id` of Image, `name` of Image Collection, or a vector of Image `id` to create a new Image Collection
`filename`	File or Asset Name
`folder`	Optional: Project Name
`parent`	Full path to project folder (with or without `"/assets"` suffix)

Value

A geedim.image.ImageAccessor (for geedim >= 2.0.0) or geedim.MaskedImage (for geedim < 2.0.0) object, or try-error on error. See \link{geedim-versions} for more details.

A geedim.collection.ImageCollectionAccessor (for geedim >= 2.0.0) or geedim.MaskedCollection (for geedim < 2.0.0) object, or try-error on error. See \link{geedim-versions} for more details.

A geedim.collection.ImageCollectionAccessor (for geedim >= 2.0.0) or geedim.MaskedCollection (for geedim < 2.0.0) object, or try-error on error. See \link{geedim-versions} for more details.

Examples

```
if (gd_is_initialized())
  gd_image_from_id('CSP/ERGo/1_0/Global/SRTM_topoDiversity')
```

```
if (gd_is_initialized())

  # Find 1m DEMs in arbitrary extent
  r <- gd_bbox(xmin = -121.4, xmax = -121.35, ymin = 37.55, ymax = 37.6)

  # collection of individual tiles of DEM
  x <- gd_collection_from_name("USGS/3DEP/1m")

  # search within region
  y <- gd_search(x, r)

  gd_properties(y)
```

```
if (gd_is_initialized())
  # Find 1m DEM in arbitrary extent
  r <- gd_bbox(xmin = -121.4, xmax = -121.35, ymin = 37.55, ymax = 37.6)

  # collection of individual tiles of DEM
  x <- gd_collection_from_name("USGS/3DEP/1m")

  # search within region
  y <- gd_search(x, r)

  # select images with some condition of interest
  z <- subset(gd_properties(y),
              grepl("UpperSouthAmerican_Eldorado_2019", id) > 0)

  # create encapsulated images from IDs returned by search
```

```
  l <- lapply(z$id, gd_image_from_id)

  # create a new collection from the list of images
  ## Not run:
  l2 <- gd_collection_from_list(l)
  l2

## End(Not run)

### download composite of custom collection
#  gd_download(gd_composite(l2),
#              filename = "test.tif",
#              region = r,
#              crs = "EPSG:5070",
#              scale = 30)

## Not run:
if (gd_is_initialized())
  gd_asset_id("RGEEDIM_TEST", "rgeedim-demo")

## End(Not run)

## Not run:
if (gd_is_initialized())
  gd_list_assets("projects/rgeedim-demo")

## End(Not run)
```

---

gd_initialize *Initialize* geedim

Description

Calls geedim `Initialize()` method. This method should be called at the beginning of each session.

Usage

```
gd_initialize(
  private_key_file = NULL,
  credentials = NULL,
  cloud_api_key = NULL,
  url = "https://earthengine-highvolume.googleapis.com",
  http_transport = NULL,
  project = NULL,
```

```
  quiet = FALSE
)

gd_is_initialized(..., quiet = TRUE)
```

Arguments

private_key_file	character. Optional: Path to JSON file containing service account credentials. (Deprecated in v0.3.0: use GOOGLE_APPLICATION_CREDENTIALS environment variable instead. If provided and GOOGLE_APPLICATION_CREDENTIALS is not set, the file path will be used to set that environment variable.)
credentials	Default: NULL uses Google Application Default Credentials (ADC) to find credentials automatically. Can be set to a pre-existing credential object if needed.
cloud_api_key	An optional API key to use the Cloud API. Default: NULL.
url	The base url for the EarthEngine REST API to connect to. Defaults to "High Volume" endpoint: "https://earthengine-highvolume.googleapis.com"
http_transport	The HTTP transport method to use when making requests. Default: NULL
project	The client project ID or number to use when making API calls. Default: NULL will check GOOGLE_CLOUD_QUOTA_PROJECT, GOOGLE_CLOUD_PROJECT then GCLOUD_PROJECT environment variables.
quiet	Suppress error messages? Default: TRUE
...	Additional arguments passed to gd_initialize()

Details

Authentication is handled automatically by Google Application Default Credentials (ADC). When credentials is NULL (the default), the underlying Python libraries will automatically search for credentials in the following order:

1. GOOGLE_APPLICATION_CREDENTIALS environment variable (if set)
2. User credentials from gcloud auth application-default login
3. Attached service account (when running on Google Cloud infrastructure)

In a headless environment (e.g. CI/CD), use GOOGLE_APPLICATION_CREDENTIALS to specify the service account key file path and GOOGLE_CLOUD_QUOTA_PROJECT to specify the project ID responsible for quota and billing.

The deprecated private_key_file parameter is provided for backward compatibility. If specified and GOOGLE_APPLICATION_CREDENTIALS is not already set, the file path will be used to set that environment variable for the Python libraries to discover.

Value

gd_initialize(): try-error (invisibly) on error.

gd_is_initialized(): logical. TRUE if initialized successfully.

See Also

gd_authenticate()

Examples

```
## Not run:
gd_initialize()

## End(Not run)
gd_is_initialized()
```

---

gd_install *Install Required Python Modules*

Description

This function installs the latest numpy, earthengine-api, and geedim modules. The default uses pip for package installation. You can configure custom environments with pip=FALSE and additional arguments that are passed to reticulate::py_install().

Usage

```
gd_install(pip = TRUE, system = FALSE, force = FALSE, version = NULL, ...)
```

Arguments

pip	Use pip package manager? Default: TRUE. To use a virtual or conda environment specify method="virtualenv" or method="conda", respectively. See details.
system	Use a system() call to python -m pip install --user ... instead of reticulate::py_install(). Default: FALSE.
force	Force update (uninstall/reinstall) and ignore existing installed packages? Default: FALSE. Applies to pip=TRUE.
version	The version of geedim to install. If NULL (the default), the latest version will be installed.
...	Additional arguments passed to reticulate::py_install()

Details

This function provides a basic wrapper around reticulate::py_install(), except it defaults to using the Python package manager pip. If you specify method="virtualenv" or method="conda then the default envname is "r-rgeedim" unless you set it to something else. If an environment of that name does not exist it is created.

Value

NULL, or try-error (invisibly) on R code execution error.

Examples

```
## Not run:

# install with pip (with reticulate)
gd_install()

# use virtual environment with default name "r-rgeedim"
gd_install(method = "virtualenv")

# use "conda" environment named "foo"
gd_install(method = "conda", envname = "foo")

# install with pip (system() call)
gd_install(system = TRUE)

## End(Not run)
```

`gd_mask_clouds` *Mask Clouds or Apply Fill Mask*

Description

Apply the cloud/shadow mask if supported, otherwise apply the fill mask.

Usage

```
gd_mask_clouds(x)
```

Arguments

`x`	a `geedim.image.ImageAccessor` (for geedim >= 2.0.0) or `geedim.mask.MaskedImage` (for geedim < 2.0.0). See `\link{geedim-versions}` for more details.

Value

a `geedim.image.ImageAccessor` (for geedim >= 2.0.0) or `geedim.mask.MaskedImage` (for geedim < 2.0.0). See `\link{geedim-versions}` for more details.

gd_projection *Get Projection Information from Google Earth Engine Asset*

Description

Get Projection Information from Google Earth Engine Asset

Usage

```
gd_projection(x)
```

Arguments

x	character ID referencing asset, or an image object (subclass of `ee.image.Image`, `geedim.image.ImageAccessor` for geedim >= 2.0.0, or `geedim.download.BaseImage` for geedim < 2.0.0). See `\link{geedim-versions}` for more details.

Value

`ee.Projection` object

Examples

```
if (gd_is_initialized())
  gd_projection(gd_image_from_id('CSP/ERGo/1_0/Global/SRTM_topoDiversity'))
```

gd_properties *Get Properties of an Image Collection*

Description

Get Properties of an Image Collection

Usage

```
gd_properties(x)
```

Arguments

x	A `geedim.collection.ImageCollectionAccessor` (for geedim >= 2.0.0) or `geedim.collection.MaskedCollection` (for geedim < 2.0.0) object. See `\link{geedim-versions}` for more details.

Value

data.frame containing properties table from x; NULL if no properties table.

Examples

```
library(terra)

b <- terra::vect('POLYGON((-121.355 37.560,
                           -121.355 37.555,
                           -121.350 37.555,
                           -121.350 37.560,
                           -121.355 37.560))',
                 crs = "OGC:CRS84")

if (gd_is_initialized()) {
  x <- gd_search(gd_collection_from_name("USGS/3DEP/1m"),
                 region = gd_region(b))
  gd_properties(x)
}
```

---

gd_region *Create GeoJSON Region from R Spatial Objects*

Description

Creates a suitable input for the region argument to gd_download(<Image>) or gd_search() for Image Collections.

gd_region_to_vect() is the inverse function of gd_region/gd_bbox; convert GeoJSON-like list to Well-Known Text(WKT)/*SpatVector*. This may be useful, for example. when gd_region()-output was derived from an Earth Engine asset rather than local R object.

Usage

```
gd_region(x)

gd_region_to_vect(x, crs = "OGC:CRS84", as_wkt = FALSE, ...)
```

Arguments

x	list. A GeoJSON-like list object (e.g. from gd_region()).
crs	character. Default for GeoJSON sources is "OGC:CRS84".
as_wkt	logical. Return Well-Known Text (WKT) string as character? Default: FALSE returns a 'terra' *SpatVector*.
...	Additional arguments to gd_region_to_vect() are passed to terra::vect() when as_wkt=FALSE (default).

Details

If x is an R spatial object, each vertex (possibly after converting object extent to vector) is used to create the GeoJSON object. Otherwise, the extent is determined and passed to gd_bbox().

gd_region_to_vect() uses Python's json module (via reticulate) to parse the GeoJSON list and terra to create the spatial vector object. It supports all geometry types handled by terra::vect (e.g., Polygon, MultiPolygon).

Value

list representing a GeoJSON extent

gd_region_to_vect(): a 'terra' *SpatVector* object, or *character* containing Well-Known Text.

See Also

gd_bbox()

Examples

```
library(terra)

b <- terra::vect('POLYGON((-121.355 37.560,
                           -121.355 37.555,
                           -121.350 37.555,
                           -121.350 37.560,
                           -121.355 37.560))',
                 crs = "OGC:CRS84")

gd_region(b)
```

---

gd_search *Search an Image Collection*

Description

Search an Image Collection

Usage

```
gd_search(
  x,
  region,
  start_date = "2000-01-01",
  end_date = as.character(Sys.Date()),
  ...
)
```

Arguments

x	A geedim.collection.ImageCollectionAccessor (for geedim >= 2.0.0) or geedim.MaskedCollection (for geedim < 2.0.0) object. See \link{geedim-versions} for more details.
region	list / Python GeoJSON object describing region, e.g. as created by gd_bbox()
start_date	Default: '2020-01-01'
end_date	Default: Sys.Date()
...	additional arguments to geedim.MaskedCollection.search() e.g. cloudless_portion, fill_portion

Value

A geedim.collection.ImageCollectionAccessor (for geedim >= 2.0.0) or geedim.MaskedCollection (for geedim < 2.0.0) object suitable for querying properties. See \link{geedim-versions} for more details.

Examples

```
b <- terra::vect('POLYGON((-121.355 37.56,-121.355 37.555,
                    -121.35 37.555,-121.35 37.56,
                    -121.355 37.56))',
          crs = "OGC:CRS84")
if (gd_is_initialized())
  gd_search(gd_collection_from_name("USGS/3DEP/1m"),
            region = gd_region(b))
```

---

gd_task_status *Get Earth Engine Task Status*

Description

gd_task_status() and gd_task_uri() are helper functions for working with tasks scheduled with gd_export()

Usage

```
gd_task_status(x)

gd_task_uri(x, asset_only = TRUE)
```

Arguments

x	An object of class "ee.batch.Task"
asset_only	Default: TRUE. For export tasks with type="asset", return only the asset ID, rather than whole URL. Other export task types return a full path to either Google Drive or Google Cloud location. When FALSE the path is a HTTPS link to an Earth Engine asset.

Value

gd_task_status(): returns the status from an "ee.batch.Task" object

gd_task_uri(): returns the destination URI(s) associated with a task.

Examples

```
## Not run:
if (gd_is_initialized()) {
  r <- gd_bbox(
    xmin = -120.6032,
    xmax = -120.5377,
    ymin = 38.0807,
    ymax = 38.1043
  )

  i <- gd_image_from_id('CSP/ERGo/1_0/US/CHILI')
  ex <- gd_export(
    i,
    region = r,
    type = "asset",
    filename = "RGEEDIM_TEST",
    folder = "rgeedim-demo",
    scale = 30
  )

  gd_task_status(ex)

  r <- gd_download(
    gd_task_uri(ex),
    filename = "image.tif",
    region = r,
    overwrite = TRUE
  )

  library(terra)
  plot(rast(r))
}

## End(Not run)
```

geedim — Module(geedim) - *Get* geedim *Module Instance*

Description

Gets the geedim module instance in use by the package in current **R**/reticulate session.

Usage

```
geedim()

gd_version()
```

Value

character. Version Number.

geedim-versions — *Handling geedim 1.x.x and 2.x.x APIs*

Description

rgeedim is designed to work with both geedim 1.x.x and 2.x.x.

API Changes

geedim 2.0.0 introduced a number of breaking changes to the API. The most notable changes are:

- The MaskedImage and MaskedCollection classes are deprecated. The ee.Image.gd and ee.ImageCollection.gd accessors should be used instead.
- The default Landsat cloud mask is more aggressive.
- MaskedCollection.stac property now returns a STAC dictionary and not a StacItem instance.
- MaskedImage doesn't add mask bands to composite images.
- When cloud masking is not supported, MaskedImage.mask_clouds() leaves the image unaltered instead of applying a fill mask.
- MaskedImage.scale is in units of its CRS, not meters.

New Features

- A new API is provided via `gd` accessors on the `ee.Image` and `ee.ImageCollection` Earth Engine classes.
- Client-side access to image and collection properties.
- Images and image collections can be exported to GeoTIFF file, NumPy array, Xarray DataArray / Dataset and Google Cloud platforms.
- Support for exporting to Cloud Optimised GeoTIFF.
- A custom `nodata` value can be set when exporting to GeoTIFF.
- Cloud masking support is extended to Landsat C2 collections.

Backward Compatibility

`rgeedim` provides a backward compatibility layer to ensure that code written for `geedim` 1.x.x continues to work with `geedim` 2.x.x. This is achieved by checking the `geedim` version at runtime and using the appropriate API.

If you need to use the old behaviors, you can pin the `geedim` version to `1.9.0` using `reticulate::virtualenv_install()`:

```
reticulate::virtualenv_install("r-rgeedim", "geedim==1.9.0")
```

Class Equivalents

geedim 1.x.x	geedim 2.x.x
`MaskedImage`	`ImageAccessor`
`MaskedCollection`	`ImageCollectionAccessor`
